# Hardware design is hard(er)

- ▶ Strict(er) correctness requirements
  - You can't simply *update* a full-custom chip after production
    - Intel FDIV
  - Expensive verification / validation (up to 50% of development costs)
- ▶ Low-level details (more) important
  - Layout / area
  - Power consumption / fault tolerance

# Hardware design is growing

- ▶ Moore's law will still apply for some time
  - We can keep packing more transistors into same silicon area
- ▶ **But** optimizations in CPUs display diminishing returns
  - Thus, more algorithms *directly* in hardware

# Hardware Description Languages

- ▶ All started in the 1980s
- ▶ *De facto* industry standards: VHDL and Verilog
- ▶ Were intended for *simulation*, not modelling or synthesis
  - *Unsynthesizable* constructs
  - Widely variable tool support

## Background

# Functional Hardware Description

- ▶ A functional program describes a circuit
- ▶ Several *functional* Hardware Description Languages (HDLs) during the 1980s
  - For example,  $\mu$ FP [Sheeran, 1984]
- ▶ Later, *embedded* hardware Domain-Specific Languages (DSLs)
  - For example, Lava (Haskell) [Bjesse et al., 1998]

# Dependently-Typed Programming

## ► Types can depend on values

- Example: `data Vec ( $\alpha$  : Set) :  $\mathbb{N} \rightarrow$  Set where...`
- Compare with Haskell (GADT style):  
`data List :: * -> * where...`

## ► Types of arguments can depend on *values of previous arguments*

- Ensure a “safe” domain
- `take : ( $m$  :  $\mathbb{N}$ )  $\rightarrow$  Vec  $\alpha$  ( $m + n$ )  $\rightarrow$  Vec  $\alpha$   $m$`

### Conclusions

Limitations  
Future work

# Dependently-Typed Programming

- ▶ Type checking requires *evaluation* of functions
  - We want `Vec Bool (2 + 2)` to unify with `Vec Bool 4`
- ▶ Consequence: all functions must be *total*
- ▶ Termination checker ensures (heuristics)
  - Structurally-decreasing recursion
    - This passes the check:  
`add :  $\mathbb{N} \rightarrow \mathbb{N} \rightarrow \mathbb{N}$`   
`add zero y = y`  
`add (suc x') y = suc (add x' y)`
    - This does not:  
`silly :  $\mathbb{N} \rightarrow \mathbb{N}$`   
`silly zero = zero`  
`silly (suc n') = silly [ n' /2 ]`

# Dependent types as logic

- ▶ Programming language / Theorem prover
  - Types as propositions, terms as proofs [Wadler, 2014]

- ▶ Example:

- Given the relation (drawn triangle):

```
data __≤__ : ℕ → ℕ → Set where
  z≤n : ∀ {n}                → zero ≤ n
  s≤s  : ∀ {m n} → m ≤ n → suc m ≤ suc n
```

- Proposition:

```
twoLEQFour : 2 ≤ 4
```

- Proof:

```
twoLEQFour = s≤s (s≤s z≤n)
s≤s (s≤s (z≤n : 0 ≤ 4) : 1 ≤ 4) : 2 ≤ 4
```

# Agda syntax for Haskell programmers

- ▶ Liberal identifier lexing (Unicode **everywhere**)
  - $a \equiv b + c$  is a valid identifier,  $a \equiv b + c$  an expression
  - Actually used in Agda's standard library
  - And in  $\Pi$ -Ware:  $\mathbb{C}$ ,  $\llbracket c \rrbracket$ ,  $\Downarrow$ ,  $\Uparrow$
- ▶ *Mixfix* notation
  - $\_[_]\_ := \_$  is the vector update function:  $v \ [ \ # \ 3 \ ] \ := \ \text{true}$ .
  - $\_[_]\_ \ v \ (\# \ 3) \ \text{true} \iff v \ [ \ # \ 3 \ ] \ := \ \text{true}$
- ▶ Almost nothing built-in
  - $\_+_ \ : \mathbb{N} \rightarrow \mathbb{N} \rightarrow \mathbb{N}$  defined in `Data.Nat`
  - $\text{if\_then\_else\_} : \text{Bool} \rightarrow \alpha \rightarrow \alpha \rightarrow \alpha$  defined in `Data.Bool`

# Agda syntax for Haskell programmers

- ▶ Implicit arguments

- Don't have to be passed if Agda can **guess** it
- Syntax:  $\varepsilon : \{ \alpha : \text{Set} \} \rightarrow \text{Vec } \alpha \text{ zero}$

► “For all” syntax:  $\forall n \iff (n : \_)$

- Where `_` means: guess this type (based on other args)
- Example:
  - $\forall n \rightarrow \text{zero} \leq n$
  - `data < : ℕ → ℕ → Set`

- ▶ It's common to combine both:

- $\forall \{ \alpha \ n \} \rightarrow \text{Vec } \alpha \ (\text{succ } n) \rightarrow \alpha \iff$   
 $\{ \alpha : \ \ \ \ \} \{ n : \ \ \ \} \rightarrow \text{Vec } \alpha \ n \rightarrow \alpha$

## Gates instance (BoolTrio)

- ▶ Defining the *interfaces* of the gates

```
[in] FalseConst# = 0
```

```
|in| TrueConst# = 0
```

```
|in| Not# = 1
```

$$|in|_{And\#} = 2$$
$$|in|_{Or\#} = 2$$
$$|out|_{-} = 1$$

- And the specification function for each gate

```
spec=false == [ false ]
```

```
spec-true      = [ true ]
```

$$\text{spec-not} \quad (x :: \varepsilon) \quad = \text{not } x$$

spec-and  $(x :: y :: \varepsilon) = [x \wedge y]$

spec-or       $(x :: y :: \varepsilon) = [x \vee y]$

# High-level circuits

- ▶ User is not supposed to describe circuits at low level ( $\mathbb{C}'$ )
- ▶ The high level circuit type ( $\mathbb{C}$ ) allows for *typed* circuit interfaces
  - The input and output indices are Agda types

```
data C (α β : Set) {i j : ℕ} : Set where
  MkC : { [ sα : ↓W↑ α {i} ] [ sβ : ↓W↑ β {j} ] }
        → C' i j → C α β {i} {j}
```

- ▶ MkC takes:
  - Low level description ( $\mathbb{C}'$ )
  - Information on how to *synthesize* elements of  $\alpha$  and  $\beta$ 
    - Passed as *instance arguments*

Missing “pieces”:

► Adapt Atomic

- New field: a **VHDLTypeDecl**
  - Such as: **type** ident **is** (elem1, elem2);
  - Enumerations, integers (ranges), records.
- New field: **atomVHDL** : **Atom#** → **VHDLExpr**

► Adapt Gates

- For each gate, a corresponding **VHDL**Entity
- **netlist** :  $(g\# : \text{Gates}\#) \rightarrow \text{VHDL} \text{Entity } (|in| \ g\#) (|out| \ g\#)$ 
  - The VHDL entity has the *interface* of corresponding gate

## Combinational simulation (excerpt)

$$\llbracket \_ \rrbracket' : \forall \{i\ o\} \rightarrow (c : \mathbb{C}'\ i\ o) \{p : \text{comb}'\ c\} \rightarrow (\mathbb{W}\ i \rightarrow \mathbb{W}\ o)$$

$$[\![\text{Nil}]\!]^{\prime} = \text{const } \varepsilon$$

$$\llbracket \text{Gate } g^\# \rrbracket' = \text{spec } g^\#$$

$$\llbracket \text{Plug } p \rrbracket' = \text{plugOutputs } p$$

$$\llbracket \text{DelayLoop } c \rrbracket' \{ () \} v$$

$$\llbracket c_1 \gg' c_2 \rrbracket' \{p_1, p_2\} = \llbracket c_2 \rrbracket' \{p_2\} \circ \llbracket c_1 \rrbracket' \{p_1\}$$

$$\llbracket \_ + ' \_ \{i_1\} \ c_1 \ c_2 \rrbracket' \{p_1, p_2\} =$$

$$\llbracket \llbracket c_1 \rrbracket' \{p_1\}, \llbracket c_2 \rrbracket' \{p_2\} \rrbracket' \circ \text{untag } \{i_1\}$$

► Remarks:

- Proof required that  $c$  is combinational
- **Gate** case uses specification function
- **DelayLoop** case can be *discharged*

# Sequential simulation

- ▶ Inputs and outputs become **Streams**
  - $\mathbb{C}' \ i \ o \implies \text{Stream} (\mathbb{W} \ i) \rightarrow \text{Stream} (\mathbb{W} \ o)$
  - **Stream**: infinite list
- ▶ We can't write a recursive evaluation function over **Streams**
  - *Sum* case needs  $\text{Stream} (\alpha \uplus \beta) \rightarrow \text{Stream} \alpha \times \text{Stream} \beta$ 
    - What if there are no *lefts* (or *rights*)?
- ▶ A stream function is not an accurate model for hardware
  - A function of type  $(\text{Stream} \alpha \rightarrow \text{Stream} \beta)$  can “look ahead”
  - For example, **tail**  $(x_0 :: x_1 :: x_2 :: xs) = x_1 :: x_2 :: xs$

# Causal stream functions

Solution: sequential simulation using *causal* stream function

Some definitions:

- ▶ Causal context: past + present values

$$\Gamma_{\mathbf{c}} : (\alpha : \mathbf{Set}) \rightarrow \mathbf{Set}$$

$$\Gamma_{\mathbf{c}} \alpha = \alpha \times \mathbf{List} \alpha$$

- ▶ Causal stream function: produces **one** (current) output

$$\_ \Rightarrow_{\mathbf{c}} \_ : (\alpha \ \beta : \mathbf{Set}) \rightarrow \mathbf{Set}$$

$$\alpha \Rightarrow_{\mathbf{c}} \beta = \Gamma_{\mathbf{c}} \alpha \rightarrow \beta$$

Universiteit Utrecht

# Causal sequential simulation

- Core sequential simulation function:

$$\begin{aligned} \llbracket \_ \rrbracket c &: \{i\ o : \mathbb{N}\} \rightarrow \mathbb{C}'\ i\ o \rightarrow (\mathbb{W}\ i \Rightarrow_c \mathbb{W}\ o) \\ \llbracket \text{Nil} \rrbracket c\ (w^0, \_) &= \llbracket \text{Nil} \rrbracket' w^0 \\ \llbracket \text{Gate } g\# \rrbracket c\ (w^0, \_) &= \llbracket \text{Gate } g\# \rrbracket' w^0 \\ \llbracket \text{Plug } p \rrbracket c\ (w^0, \_) &= \text{plugOutputs } p\ w^0 \\ \llbracket \text{DelayLoop } c\ \{p\} \rrbracket c &= \text{take}_v\ j \circ \text{delay } c\ \{p\} \end{aligned}$$

$$\llbracket c_1 \gg' c_2 \rrbracket c = \llbracket c_2 \rrbracket c \circ \text{map}^+ \llbracket c_1 \rrbracket c \circ \text{tails}^+$$

- Nil, Gate and Plug cases use combinational simulation
- DelayLoop calls a recursive helper (delay)
- Example structural case:  $\_ \gg' \_$  (sequence)
  - Context of  $\llbracket c_1 \rrbracket c$  is context of the whole compound
  - Context of  $\llbracket c_2 \rrbracket c$  is past and present *outputs* of  $c_1$

# Sequential simulation

- ▶ We can then “run” the step-by-step function to produce a whole **Stream**

- Idea from “The Essence of Dataflow Programming” [Uustalu and Vene, 2005]

$\text{runc}' : (\alpha \Rightarrow_{\mathbf{c}} \beta) \rightarrow (\Gamma_{\mathbf{c}} \alpha \times \text{Stream } \alpha) \rightarrow \text{Stream } \beta$

$\text{runc}' f ((x^0, x^-), (x^1 :: x^+)) =$   
 $f (x^0, x^-) :: \# \text{runc}' f ((x^1, x^0 :: x^-), \mathbf{b} x^+)$

$\text{runc} : (\alpha \Rightarrow_{\mathbf{c}} \beta) \rightarrow (\text{Stream } \alpha \rightarrow \text{Stream } \beta)$

$\text{runc } f (x^0 :: x^+) = \text{runc}' f ((x^0, []), \mathbf{b} x^+)$

- ▶ Obtaining the stream-based simulation function:

$\llbracket \_ \rrbracket *' : \forall \{i \ o\} \rightarrow \mathbb{C}' \ i \ o \rightarrow (\text{Stream } (\mathbf{W} \ i) \rightarrow \text{Stream } (\mathbf{W} \ o))$

$\llbracket \_ \rrbracket *' = \text{runc} \circ \llbracket \_ \rrbracket_{\mathbf{c}}$

## Properties of circuits

- ▶ Tests and proofs about circuits depend on the *semantics*
  - We focused on the functional simulation semantics
  - Other possibilities (gate count, critical path, etc.)
- ▶ Very simple sample circuit to illustrate: XOR

# Specification of XOR

- ▶ To define *correctness* we need a *specification function*
  - Listing all possibilities (truth table)
  - Based on pre-existing functions (standard library)
- ▶ Truth table

$\underline{\text{VC}}\text{-spec-table} : (B \times B) \rightarrow B$

$\underline{\text{VC}}\text{-spec-table} \text{ (false , false) } = \text{false}$

$\underline{\text{VC}}\text{-spec-table} \text{ (false , true) } = \text{true}$

$\underline{\text{VC}}\text{-spec-table} \text{ (true , false) } = \text{true}$

$\underline{\text{VC}}\text{-spec-table} \text{ (true , true) } = \text{false}$

# Proof of XOR (truth table)

$\underline{\vee}\mathbb{C}\text{-proof-table} : [\![ \underline{\vee}\mathbb{C} ]\!] (a, b) \equiv \underline{\vee}\mathbb{C}\text{-spec-table} (a, b)$

$\underline{\vee}\mathbb{C}\text{-proof-table} \text{ false false} = \text{refl}$

$\underline{\vee}\mathbb{C}\text{-proof-table} \text{ false true} = \text{refl}$

$\underline{\vee}\mathbb{C}\text{-proof-table} \text{ true false} = \text{refl}$

$\underline{\vee}\mathbb{C}\text{-proof-table} \text{ true true} = \text{refl}$

- Proof by *case analysis*
  - Could be automated (reflection)

# Specification of XOR

- ▶ Based (`_xor_`) from `Data.Bool`

`_xor_` :  $B \rightarrow B \rightarrow B$

`true xor b = not b`

`false xor b = b`

- ▶ Adapted interface to match exactly `⊔`

`⊔-spec-subfunc` :  $(B \times B) \rightarrow B$

`⊔-spec-subfunc = uncurry' _xor_`

## Proof of XOR (pre-existing)

- Proof based on  $\forall C\text{-spec-subfunc}$

$$\underline{\text{VC-proof-subfunc}} : \llbracket \underline{\text{VC}} \rrbracket (a, b) \equiv \underline{\text{VC-spec-subfunc}} (a, b)$$

$$\underline{\text{VC-proof-subfunc}} = \underline{\text{VC-xor-equiv}}$$

- ▶ Need a lemma to complete the proof
  - Circuit is defined using {NOT, AND, OR}
  - xor is defined directly by pattern matching

$$\text{vC-xor-equiv} : (\text{not } a \wedge b) \vee (a \wedge \text{not } b) \equiv (a \text{ xor } b)$$

## Circuit “families”

- ▶ We can also prove properties of circuit “families”
- ▶ Example: an AND gate with a generic number of inputs

$$\text{and } N' : \forall n \rightarrow \mathbb{C}'_n \quad 1$$

and  $N'_{\text{zero}} = TC'$

$$\text{andN}'(\text{suc } n) = \text{idC}' \mid' \text{andN}' n \gg' \wedge \text{C}'$$

- ▶ Example proof: when all inputs are high, output is high
  - For *any* number of inputs
  - Proof by induction on  $n$  (number of inputs)

# Problems

- This proof is done in the *low level*

$$\begin{aligned}\text{proof-andN}' &: \forall n \rightarrow \llbracket \text{andN}' n \rrbracket' (\text{replicate true}) \equiv [ \text{true} ] \\ \text{proof-andN}' \text{ zero} &= \text{refl} \\ \text{proof-andN}' (\text{suc } n) &= \text{cong } (\text{spec-and} \circ (\_ :: \_ \text{ true})) \\ &\quad (\text{proof-andN}' n)\end{aligned}$$

- Still problems with inductive proofs in the high level
  - Guess: definition of  $\mathbb{C}$  and  $\llbracket \_ \rrbracket$  prevent goal reduction
