Syntax Semantics **Proofs** 

#### Conclusions

Limitations Future work

## Hardware design is hard(er)

- ▶ Strict(er) correctness requirements
  - You can't simply update a full-custom chip after production
    - Intel FDTV
  - Expensive verification / validation (up to 50% of development costs)
- ▶ Low-level details (more) important
  - Layout / area
  - Power consumption / fault tolerance

#### roofs

Conclusions

#### Limitations

## Hardware design is growing

- ▶ Moore's law will still apply for some time
  - We can keep packing more transistors into same silicon area
- ▶ **But** optimizations in CPUs display diminishing returns
  - Thus, more algorithms directly in hardware

emantics

Conclusions

## Hardware Description Languages

- ▶ All started in the 1980s
- ▶ De facto industry standards: VHDL and Verilog
- ▶ Were intended for *simulation*, not modelling or synthesis
  - Unsynthesizable constructs
  - Widely variable tool support

## Functional Hardware Description

- A functional program describes a circuit
- Several functional Hardware Description Languages (HDLs) during the 1980s
  - For example,  $\mu$ FP [Sheeran, 1984]
- ▶ Later, embedded hardware Domain-Specific Languages (DSLs)
  - For example, Lava (Haskell) [Bjesse et al., 1998]

### Research Question

"What are the improvements that DTP can bring to hardware design?"

Question

## Methodology

- Develop a hardware DSL, embedded in a dependently-typed language (Agda)
  - Called **Π-Ware**
  - allowing simulation, synthesis and verification

Background

Functional Hardwa

Research

Method

DTP / Agda

Big picture

∏\_Ware

I I-VVare

Semantics

onclusion

Limitations

- Types can depend on values
  - Example: data Vec (α : Set) : N → Set where...
  - Compare with Haskell (GADT style):
     data List :: \* -> \* where...
- Types of arguments can depend on values of previous arguments
  - Ensure a "safe" domain
  - take :  $(m : \mathbb{N}) \to \text{Vec } \alpha \ (m+n) \to \text{Vec } \alpha \ m$

Hardware Design
Functional Hardware

Research Question

Method

DTP / Agda

Big picture

Agda

Π-Ware

emantics

Conclusions

- ▶ Type checking requires *evaluation* of functions
  - We want Vec Bool (2 + 2) to unify with Vec Bool 4
- ▶ Consequence: all functions must be total
- ► Termination checker ensures (heuristics)
  - Structurally-decreasing recursion
    - This passes the check:

```
\begin{array}{ll} \mathrm{add} \,:\, \mathbb{N} \to \mathbb{N} \to \mathbb{N} \\ \mathrm{add} \,\, \mathrm{zero} & y = y \\ \mathrm{add} \,\, (\mathrm{suc} \,\, x') & y = \mathrm{suc} \,\, (\mathrm{add} \,\, x' \,\, y) \end{array}
```

· This does not:

```
silly : \mathbb{N} \to \mathbb{N}

silly zero = zero

silly (suc n') = silly | n' /2|
```

### Hardware Design

Functional Hardwa

Method

DTP / Agda

#### Big picture

Agda

#### I I-Ware

Semantics

### Conclusions

Dependent pattern matching can rule out impossible cases

Big picture

▶ Dependent pattern matching can *rule out* impossible cases

```
    Classic example: safe head function
```

 $\mathsf{head}\,:\,\mathsf{Vec}\,\,\alpha\,\,(\mathsf{suc}\,\,n)\,\to\,\alpha$ 

 $\mathsf{head}\ (x :: xs) = x$

Method

DTD / And

Big picture

Ngda

Π-Ware

Syntax Semantics

Conclusions

Limitations Future work

## Depedent types as logic

- Programming language / Theorem prover
  - Types as propositions, terms as proofs [Wadler, 2014]
- ► Example:
  - Given the relation (drawn triangle):

```
data \_ \le \_ : \mathbb{N} \to \mathbb{N} \to \text{Set where}

z \le n : \forall \{n\} \to \text{zero} \le n

s \le s : \forall \{m \ n\} \to m \le n \to \text{suc } m \le \text{suc } n
```

Proposition:

```
twoLEQFour : 2 \le 4
```

• Proof:

```
twoLEQFour = s \le s (s \le s z \le n)

s \le s (s \le s (z \le n : 0 \le 4) : 1 \le 4) : 2 \le 4
```

Method

DTP / Agda

Big picture

Agda

I I-VVare

emantics

Conclusions

## Agda syntax for Haskell programmers

- ► Liberal identifier lexing (Unicode everywhere)
  - $a\equiv b+c$  is a valid identifer,  $a\equiv b+c$  an expression
  - · Actually used in Agda's standard library
  - And in Π-Ware: C, [ c ], ↓, ↑
- ▶ Mixfix notation
  - \_[\_]≔\_ is the vector update function: v [ # 3 ] ≔ true.
  - \_[\_]:=\_ v (# 3) true ⇔ v [ # 3 ] := true
- ▶ Almost nothing built-in
  - $\_+\_$ :  $\mathbb{N} \to \mathbb{N} \to \mathbb{N}$  defined in Data.Nat
  - if then else : Bool ightarrow lpha 
    ightarrow lpha 
    ightarrow lpha defined in Data.Bool

## Agda syntax for Haskell programmers

- Implicit arguments
  - Don't have to be passed if Agda can guess it
  - Syntax:  $\varepsilon$  :  $\{\alpha : \mathsf{Set}\} \to \mathsf{Vec} \ \alpha \ \mathsf{zero}$
- ▶ "For all" syntax:  $\forall n \iff (n : \_)$ 
  - Where \_ means: guess this type (based on other args)
  - Example:
    - $\forall n \rightarrow \text{zero} \leq n$
    - data  $\_\leq\_$ :  $\mathbb{N} \to \mathbb{N} \to \mathsf{Set}$
- ▶ It's common to combine both:
  - $\forall \{\alpha \ n\} \rightarrow \mathsf{Vec} \ \alpha \ (\mathsf{suc} \ n) \rightarrow \alpha \Longleftrightarrow \{\alpha : \_\} \{n : \_\} \rightarrow \mathsf{Vec} \ \alpha \ n \rightarrow \alpha$

Big picture Aøda

Π-Ware

Syntax

Proofs

Conclusions Limitations

## Atomic instance (Bool)

▶ Bijection between  $\{n \in \mathbb{N} \mid n < 2\}$  (Fin 2) and Bool

```
n \rightarrow B = \lambda { False# \rightarrow false; True# \rightarrow true }
B \rightarrow n = \lambda { false \rightarrow False#; true \rightarrow True# }
```

▶ Proof that  $n \rightarrow B$  and  $B \rightarrow n$  are inverses

```
inv-left-B = \lambda { False# \rightarrow refl; True# \rightarrow refl; }
inv-right-B = \lambda { false \rightarrow refl; true \rightarrow refl }
```

With all pieces at hand, we construct the instance

```
Atomic-B = record { Atom
                                      = B
                        |Atom|-1| = |B|-1
                        ; n \rightarrow atom = n \rightarrow B
                        ; atom\rightarrown = B\rightarrown
                        : inv-left = inv-left-B
                        ; inv-right = inv-right-B }
```

Syntax

Universiteit Utrecht

#### Gates

- ▶ Circuits parameterized by collection of *fundamental gates*
- Examples:
  - {NOT, AND, OR} (BoolTrio)
  - {NAND}
  - · Arithmetic, Crypto, etc.
- ► The definition of what means to be such a collection is in PiWare.Gates.Gates

# Combinational simulation (excerpt)

```
[\![ ]\!]': \forall \{i \ o\} \rightarrow (c: \mathbb{C}' \ i \ o) \{p: \mathsf{comb}' \ c\} \rightarrow (\mathsf{W} \ i \rightarrow \mathsf{W} \ o)
   [Ni] ]' = const \varepsilon
   [ Gate g# ] ' = spec g#
      [\![ Plug p ]\!]' = plugOutputs p
      [\![ DelayLoop \ c \ ]\!]' \{()\} \ v
[ c_1 \rangle \rangle c_2 \rangle \langle c_2 \rangle \langle c_1 \rangle \langle c_2 \rangle \langle c_
[ ] _{-}| +'_{-} \{i_{1}\} c_{1} c_{2} ]' \{p_{1}, p_{2}\} =
                                                 [ [ c_1 ]' \{ p_1 \}, [ c_2 ]' \{ p_2 \} ]' \circ \text{untag } \{ i_1 \}
```

#### Remarks:

- ullet Proof required that c is combinational
- Gate case uses specification function
- DelayLoop case can be discharged

Semantics

# Sequential simulation

- ▶ Inputs and outputs become Streams
  - $\mathbb{C}'$  i  $o \Longrightarrow \mathsf{Stream} (\mathsf{W} \ i) \to \mathsf{Stream} (\mathsf{W} \ o)$
  - Stream: infinite list
- ▶ We can't write a recursive evaluation function over Streams
  - Sum case needs Stream  $(\alpha \uplus \beta) \to \text{Stream } \alpha \times \text{Stream } \beta$ 
    - What if there are no lefts (or rights)?
- ▶ A stream function is not an accurate model for hardware
  - A function of type (Stream  $\alpha \to \text{Stream } \beta$ ) can "look ahead"
  - For example, tail  $(x_0 :: x_1 :: x_2 :: xs) = x_1 :: x_2 :: xs$

Background Hardware Design Functional Hardware

Research

Question

DTP / Agda

Big picture

Π-Ware

Semantics

Proofs

Limitations

### Causal stream functions

# Solution: sequential simulation using causal stream function

### Some definitions:

► Causal context: past + present values

$$\Gamma c : (\alpha : Set) \rightarrow Set$$
  
 $\Gamma c \alpha = \alpha \times List \alpha$ 

► Causal stream function: produces **one** (current) output

$$\_\Rightarrow c\_ : (\alpha \ \beta : Set) \to Set$$
  
 $\alpha \Rightarrow c \ \beta = \Gamma c \ \alpha \to \beta$ 

Hardware Design
Functional Hardware

Research Duestion

Method

DTP / Agda

Agda

∏-Ware

Semantics

roofs

Limitations

# Causal sequential simulation

Core sequential simulation function:

- ▶ Nil, Gate and Plug cases use combinational simulation
- DelayLoop calls a recursive helper (delay)
- ► Example structural case: \_\"/\_ (sequence)
  - Context of  $[c_1]$  c is context of the whole compound
  - Context of  $[\![ c_2 ]\!]$ c is past and present *outputs* of c1

Background
Hardware Design
Functional Hardware

lesearch

Method

DTP / Agda

Big picture Agda

∏-Ware

Semantics

Proofs

Conclusions

# Sequential simulation

- ▶ We can then "run" the step-by-step function to produce a whole Stream
  - Idea from "The Essence of Dataflow Programming" [Uustalu and Vene, 2005]

$$\begin{split} \operatorname{runc}' &: (\alpha \Rightarrow \operatorname{c} \beta) \to (\operatorname{\Gammac} \alpha \times \operatorname{Stream} \alpha) \to \operatorname{Stream} \beta \\ \operatorname{runc}' &f ((x^0 \,,\, x^-) \,,\, (x^1 \, \colon \colon x^+)) = \\ &f (x^0 \,,\, x^-) \, \colon \colon \sharp \operatorname{runc}' \, f \, ((x^1 \,,\, x^0 \, \colon \colon x^-) \,,\, \flat \,\, x^+) \end{split}$$

runc : 
$$(\alpha \Rightarrow c \beta) \rightarrow (\text{Stream } \alpha \rightarrow \text{Stream } \beta)$$
  
runc  $f(x^0 :: x^+) = \text{runc'} f((x^0, []), \flat x^+)$ 

▶ Obtaining the stream-based simulation function:

$$[] *' : \forall \{i \ o\} \rightarrow \mathbb{C}' \ i \ o \rightarrow (Stream \ (W \ i) \rightarrow Stream \ (W \ o))$$

 $[\![\_]\!]*' = \mathsf{runc} \circ [\![\_]\!]\mathsf{c}$

# Specification of XOR

▶ Based (\_xor\_) from Data.Bool

$$\_xor\_: B \rightarrow B \rightarrow B$$
  
true  $xor b = not b$   
false  $xor b = b$ 

► Adapted interface to match exactly <u>∨</u>ℂ

```
\ensuremath{\underline{\vee}} \mathbb{C}\text{-spec-subfunc} : (B \times B) \to B
\ensuremath{\underline{\vee}} \mathbb{C}\text{-spec-subfunc} = uncurry' _xor_
```

Proofs

Conclusions
Limitations

# Proof of XOR (pre-existing)

▶ Proof based on <u>V</u>C-spec-subfunc

$$\underline{\vee}\mathbb{C}$$
-proof-subfunc :  $[\![\underline{\vee}\mathbb{C}\,]\!]$   $(a\ ,\ b) \equiv \underline{\vee}\mathbb{C}$ -spec-subfunc  $(a\ ,b)$ 

- Need a lemma to complete the proof
  - Circuit is defined using {NOT, AND, OR}
  - xor is defined directly by pattern matching

```
\vee \mathbb{C}-xor-equiv : (not a \wedge b) \vee (a \wedge not b) \equiv (a \times b)
```

Proofs

### Circuit "families"

- ▶ We can also prove properties of circuit "families"
- ▶ Example: an AND gate with a generic number of inputs

```
andN' : \forall n \to \mathbb{C}' n 1
andN' zero = \mathbb{T}\mathbb{C}'
andN' (suc n) = id\mathbb{C}' |' andN' n \rangle' \wedge \mathbb{C}'
```

- ▶ Example proof: when all inputs are high, output is high
  - For any number of inputs
  - Proof by induction on n (number of inputs)

Proofs

Conclusions

### **Problems**

▶ This proof is done in the *low level* 

```
proof-andN': \forall n \rightarrow [\![ andN' n ]\!]' (replicate true) \equiv [\![ true \![Question
proof-andN' zero
                          = refl
proof-andN' (suc n) = cong (spec-and \circ (_::_ true))
                                    (proof-andN' n)
```

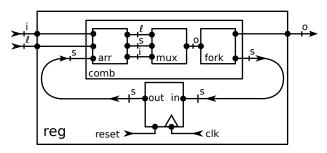

- Still problems with inductive proofs in the high level
  - Guess: definition of ℂ and □ prevent goal reduction

Proofs

# Sequential proofs

▶ Example of sequential circuit: a register

Respective Π-Ware circuit description

```
reg : \mathbb{C} (B \times B) B
reg = delay\mathbb{C} (arr ) mux2to1 ) \times \mathbb{C}
      where arr = (\uparrow \downarrow \mathbb{C} \mid | id\mathbb{C}) \rangle ALR\mathbb{C} \rangle (id\mathbb{C} \mid | \uparrow \downarrow \mathbb{C})
```

Proofs

# Register example

▶ Example (test case) of register behaviour

```
loads inputs: Stream Bool
loads = true:: # (true :: # (false :: # repeat false))
inputs = true :: # (false :: # (true :: # repeat false))
actual = take 42 (  reg  * zipWith _, _ inputs loads)
test-reg = actual = true < false < replicate false
```
